Abstract
Introduction. Inflammatory bowel disease is a complex disease which arises as a result of an interaction between environmental and genetic factors leading to immunological responses and inflammation in the intestine.
Aim. To review medical approaches used in inflammatory bowel disorders.
Materials and methods. An analysis of literature regarding inflammatory bowel diseases, Leśniowski-Crohn’s disease, ulcerative colitis and metalloproteinases.
Results. Current evidence suggests that patients with inflammatory bowel disease may have an elevated risk of endothelial dysfunction and coronary artery disease. Over the past two decades, great advances have been made in our understanding of the interplay between the inflammatory bowel disease.
Conclusions. Inflammatory bowel diseases are increasing in Europe. The diagnosis is usually confirmed by biopsies on colonoscopy.
Keywords. inflammatory bowel diseases, Leśniowski-Crohn’s disease, ulcerative colitis, metalloproteinases

Introduction
Chronic inflammatory bowel diseases are divided into Leśniowski-Crohn’s disease, ulcerative colitis and undetected colitis.1,2 Inflammatory changes in ulcerative colitis include mucosa and occur continuously from the rectum to the more proximal parts of the colon. In Leśniowski-Crohn’s disease, the changes may include the entire digestive tract.3 The symptoms include diarrhea, frequent bloody stools, and abdominal pain. Most patients with non-specific inflammatory bowel diseases from the moment of diagnosis are treated conservatively. However, a significant group of patients do not undergo such therapy during the course of the disease and require surgical procedures. Indications for surgical treatment depend on the efficacy and success of conservative treatment, the severity of the disease, and associated complications. Due to clinical differences, Leśniowski-Crohn’s disease is character-
ized by a different specialty of surgical treatment than ulcerative colitis.7

Material and methods
We reviewed the literature regarding the chronic inflammatory bowel diseases published between 1945 and 2018 (Figure 1). We found more than 500 articles studying this type of chronic inflammatory bowel diseases such as Leśniowski-Crohn’s disease, ulcerative colitis and undetected colitis. Our review includes recent studies regarding Leśniowski-Crohn’s disease, ulcerative colitis and undetected colitis.

Results
In Leśniowski-Crohn’s disease, about 50-80% of patients require surgical treatment during the course of the disease.1-5 The correct diagnosis of nonspecific inflammatory bowel diseases relies on a multidisciplinary approach based on clinical, laboratory, endoscopic, and histologic examination.

Indications for planned surgery are:8-10
- ineffective conservative treatment,
- incomplete occlusion,
- accessing cachexia, intraabdominal abscesses and internal or external fistulas, which cause malabsorption syndrome,
- severe parenteral symptoms,
- perianal lesions (fistulas, perianal abscesses, anal stenosis, anal fissures),
- intestinal epithelium or dysplasia,
- children’s developmental delay,

Urgent indications:11-12
- hemorrhage,
- occlusion,
- perforation,
- abdominal or perirectal dissemination causing sepsis, fulminant disease or acute phase of disease that does not undergo pharmacological treatment.

In the surgical treatment of Leśniowski-Crohn’s disease concerning the small intestine, the rule of economical resections applies, and the resection limits are determined by macroscopic changes and the mesenteric Fazio symptom (assessment of the mesentery infiltration thickness).

In the treatment of colorectal cholangitis, the extent and type of surgery depends on the severity and extent of the disease, the status of the colon and rectal susceptibility, functional sphincter efficiency and the extent of previous resections. It is recommended to perform a colectomy with ileo-rectum Anastomosis (in the absence of changes in the rectum) or proctocolectomy with definitive ileostomy (if the rectum is altered diseased).

Surgical treatment of ulcerative colitis is fundamentally different from the surgical treatment of Crohn’s disease. In ulcerative colitis, the aim of the operation is to remove the entire large intestine and rectal mucosa. After the procedure, the quality of life of the vast majority of patients improves. The necessity of surgical treatment is in the group of 20-25% of Colitis Ulcerosa patients.

Indications for planned surgery are:
- solid symptoms of exacerbation of the disease, despite the optimal conservative treatment
- a large intestine or a pre-cancerous lesion in the large intestine (dysplasia associated lesion or mass-DALM or flat-dysplasia)
- some local complications (occurring rarely in ulcerative colitis) such as narrowing of the colon, or internal fistulas (e.g., recto-stitch) or external
- growth and maturation delay in children

Urgent indications are:
- a severe disease that does not undergo intensive 7-10 days of conservative treatment followed by emergency treatment with cyclosporin or infliximab,
- toxic distension of the colon (megacolon toxicum, when intensive conservative treatment lasting from 24 to 48 hours did not bring any improvement)

Emergency indications:
- production of the large intestine with diffuse fecal peritonitis,
- massive bleeding,
- elastic bowel disease,

The surgery of choice for urgent or urgent indications is a colectomy with ileostomy with an occluded stump of the rectum (Hartmann’s operation) or sewn into the skin over the pubic symphysis.

Currently, is possible to achieve the expected therapeutic results and elimination/reduction of the risk of physical development. The planned indications are: complete proctocolectomy with the final ileostomy using the Brooke method; complete reconstructive proctocolectomy with intestinal ileum (pouch) and anastomosis.
of the anal canal (ileo-pouch anal anastomosis - IPAA). The technique of treatment in the case of inflammatory bowel diseases differs from that used in oncology, the wide excision of mesorectum tissues is not justified and the preparation should be conducted close to the rectum wall in order to minimize the risk of postoperative disorders of sexual function, micturition or defecation. However, surgical treatment is not a perfect and final therapeutic solution in non-specific inflammatory bowel diseases. Operations in Crohn’s disease are characterized by a large number of adverse effects (e.g. metabolic consequences of short bowel syndrome), complications and relapses, both early and late. Specification of those patients in whom surgical treatment could be characterized by a more severe postoperative course, higher risk of complications and recurrences of the disease would allow more precise selection of qualification criteria, adjust the time of surgical intervention or special surveillance to improve treatment outcomes.

In the current arsenal of laboratory, imaging and endoscopic examinations there is no marker that would allow such selection of patients. Based on the analysis of over 500 papers described nonspecific inflammatory bowel diseases, endoscopic evaluation is the main diagnostic process. Laboratory tests in the diagnosis of inflammatory bowel diseases play an auxiliary role. The most important currently known markers for nonspecific inflammatory bowel diseases are presented in Table 1.

Although considerable progress in the research has been achieved, there is still a long way to go toward the ultimate goal of an ideal biomarker in nonspecific inflammatory bowel diseases.21-31

Inflammatory Markers Belonging to Extracellular Matrix

Inflammatory bowel diseases have biomarkers which can be used to predict disease and treatment outcomes.32 The Extracellular Matrix components are depolymerized into the small fragments, which are released into circulation.33 ECM is composed of fibrous proteins and glycosaminoglycans (GAGs) and is involved in proliferation, migration, and adhesion.34-36 Sulfated GAG types are connected with the intestinal epithelium and regulate its permeability.37-38
